1 Review

An equilibrium can be thought to be comprised of three components:

1. What gets consumed?
2. What gets produced?
 - (a) **What goods are produced and how much?**
 - (b) What factors are used and how much?
3. What prices make this exchange work?

1.1 Two sector models

The economy is endowed with two production processes (sectors) f_A and f_B that produce goods A and B respectively. It is a two sector model because each sector produces a unique good.

We typically assume there are two factors of production, capital (k) and labor (l) that move freely between the two sectors.

The production functions are assumed to satisfy:

A.1 The production function f_j is twice continuously differentiable with $f'_j > 0$ and $f''_j < 0$. ✓

A.2 The production function satisfies Inada condition (this is important because ... *who has the time to check for corner solutions?*) ✓

$$\lim_{k \rightarrow 0} \frac{\partial f_j(k, l)}{\partial k} = \lim_{l \rightarrow 0} \frac{\partial f_j(k, l)}{\partial l} = +\infty \quad (1)$$

A.3 f_j is homogenous of degree 1 (constant returns to scale).

Min. cost of prod 5 units of j = 5x min. cost of 1 unit of j .

1.2 HOV model

Consider a small open economy trading goods A and B in a large world market. Consequently, prices p_A and p_B are determined independently of production here. The economy is endowed with endowments of factor inputs K and L .

1.2.1 Producer feasibility and efficiency

The PPS can be written as:

$$PPS = \{(y_A, y_B) : y_j \leq f_j(k_j, l_j) \forall j \in \{A, B\}, \overbrace{k_A + k_B \leq K}, \overbrace{l_A + l_B \leq L}\} \quad (2)$$

The production possibility frontier (PPF) are the set of all (y_A, y_B) pairs that simultaneously solves:

$$\begin{aligned} \phi(y_B) &= \max f_A(k_A, l_A) \\ \text{s. t. } &f_B(k_B, l_B) \geq y_B \\ &k_A + k_B \leq K \\ &l_A + l_B \leq L \end{aligned}$$

and

$$\begin{aligned} \phi(y_A) &= \max f_B(k_B, l_B) \\ \text{s. t. } &f_A(k_A, l_A) \geq y_A \\ &k_A + k_B \leq K \\ &l_A + l_B \leq L \end{aligned}$$

Condition on directing l_A & k_A to produce at least y_A , what's the max. amount of y_B I can make.

1.2.2 Equilibrium

Define any equilibrium as $\left(\overbrace{w^*, r^*}^{\text{factor prices}}, (l_j^*, k_j^*, y_j^*)_{j \in \{A, B\}} \right)$ such that:

1. $(l_j^*, k_j^*, y_j^*)_{j \in \{A, B\}}$ maximizes profit:

$$l_j^*, k_j^*, y_j^* = \arg \max p_j y_j - r^* k_j - w^* l_j \text{ s. t. } y_j \leq f(k_j, l_j) \quad (3)$$

2. $\sum_j (l_j^*, k_j^*) = (L, K)$

We know from lecture that there are two classes of equilibria here:

- Diversified

- Specialized

But first, recall that Shepard's lemma gives us the factor use as the gradient of the unit cost functions:

$$l_j = \frac{\partial c_j(w, r)}{\partial w}, \quad k_j = \frac{\partial c_j(w, r)}{\partial r} \quad (4)$$

Cost function:

$$C_j(\underbrace{w, r}_{\text{factor prices}}, \underbrace{q_j}_{\substack{\uparrow \\ \text{units to be produced}}}) = \min_{l, k} \quad w l + r k \quad \text{s.t.} \quad f_j(k, l) \geq q_j \\ k, l \geq 0$$

Unit output cost function:

$$c_j(w, r) \equiv C_j(w, r, 1)$$

By HOD 1 of f_j : $C_j(w, r, y) = y c_j(w, r)$.

Any eqbm satisfies: "should be" by complementary slackness

$$\begin{aligned} \text{w.r.} \quad (+) \quad & \gamma_A (p_A - c_A(w, r)) \geq 0 \\ & \gamma_B (p_B - c_B(w, r)) \geq 0 \end{aligned} \quad \left. \begin{array}{l} \text{Q: What happens when } \gamma_A, \gamma_B > 0? \\ p_A = c_A \quad \& \quad p_B = c_B \end{array} \right\}$$

$$\begin{aligned} (+) \quad & \gamma_A \begin{bmatrix} \frac{\partial c_A(w, r)}{\partial r} \\ \frac{\partial c_A(w, r)}{\partial w} \end{bmatrix} + \gamma_B \begin{bmatrix} \frac{\partial c_B(w, r)}{\partial r} \\ \frac{\partial c_B(w, r)}{\partial w} \end{bmatrix} = \begin{bmatrix} K \\ L \end{bmatrix} \end{aligned}$$

Shepard: k_A, k_B (pointing to $\frac{\partial c_A}{\partial r}, \frac{\partial c_B}{\partial r}$)
 k_A (pointing to $\frac{\partial c_A}{\partial w}$)
 k_B (pointing to $\frac{\partial c_B}{\partial w}$)

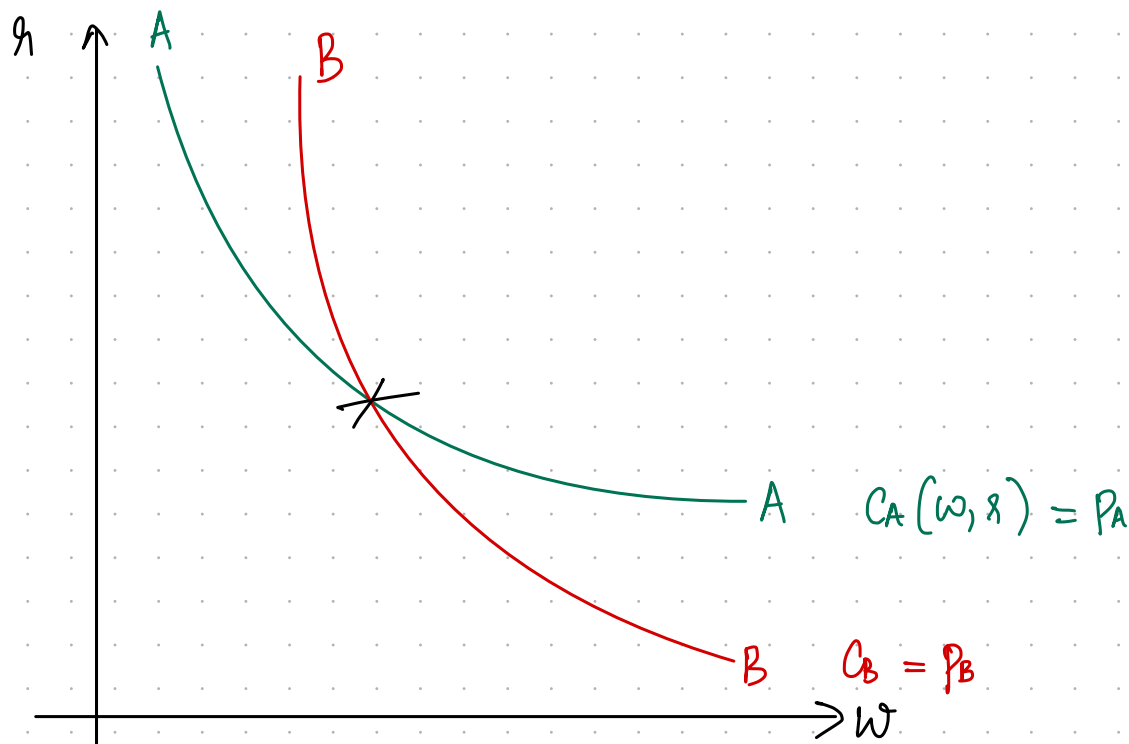

There are 2 types of specialized eqbm.

① $c_A(w, r) = p_A$ but $c_B(w, r) > p_B$.

$\Rightarrow y_B = 0$

Note that even when $y_A > 0$, $\pi_A = 0$.

② The interesting kind:

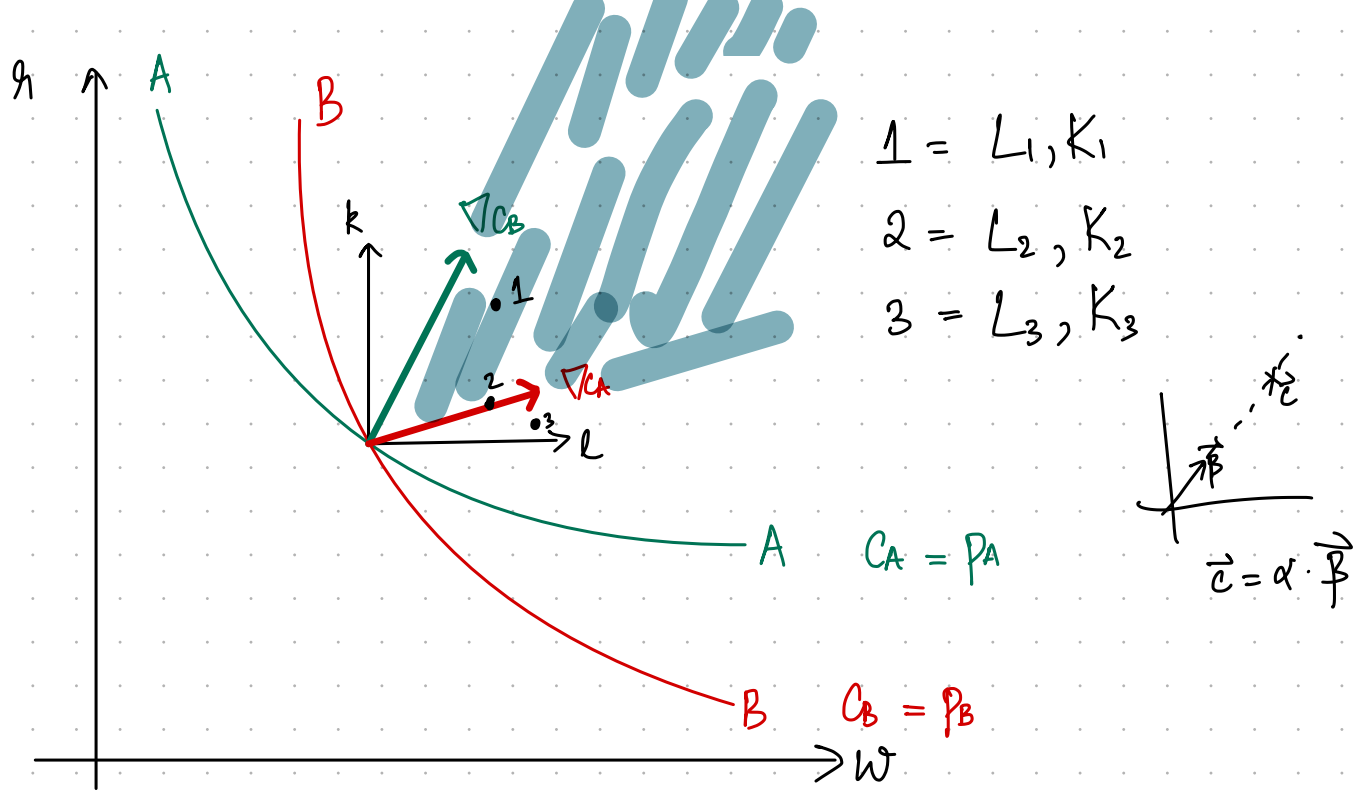

* These are the unit isoquant lines for A, B.

By Shepard's lemma, we know:

~~the~~ $\frac{\partial c_j(w, r)}{\partial w} = l_j$, $\frac{\partial c_j(w, r)}{\partial r} = k_j$.

w, r \rightarrow $c_A(w, r) = p_A$ and $c_B(w, r) = p_B$ happens where?

\rightarrow Notice that this determines w^*, r^* .

(1) $\exists \gamma_A, \gamma_B > 0$:
 $\gamma_A \nabla C_A + \gamma_B \nabla C_B = (L_1, K_1)$ } Diversified Eqbm

(2) $\exists \gamma_A > 0, \gamma_B = 0$:
 $\gamma_A \nabla C_A = (L_2, K_2)$ } Boundary Eqbm.

(3) $\nexists \gamma_A, \gamma_B > 0$: $\gamma_A \nabla C_A + \gamma_B \nabla C_B = (L_3, K_3)$.

Clearly $\gamma_A^* = 0$.

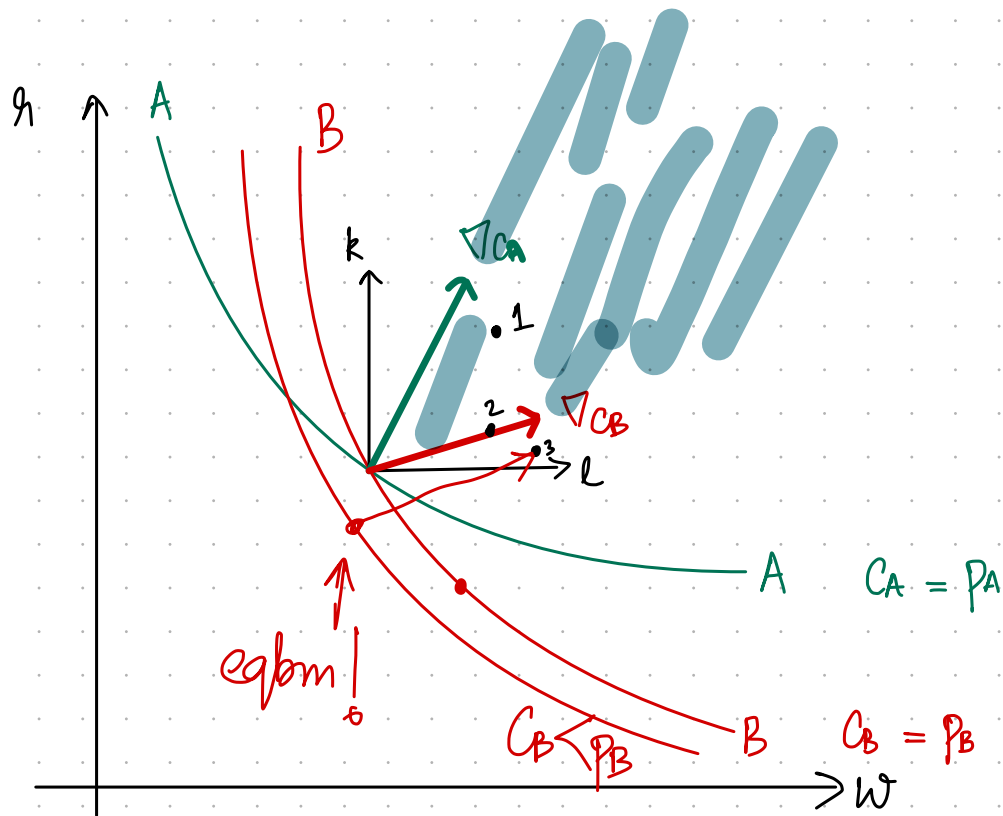

But $\gamma_B^* > 0$ as w^*, r^* such that $c_B(w^*, r^*) = p_B$

cannot satisfy $\gamma_B^* \nabla C_B^* = (L_3, K_3)$.

So, lower w^*, r^* until $c_B(w^*, r^*) < p_B$
 $\Rightarrow B$ earns positive profit.

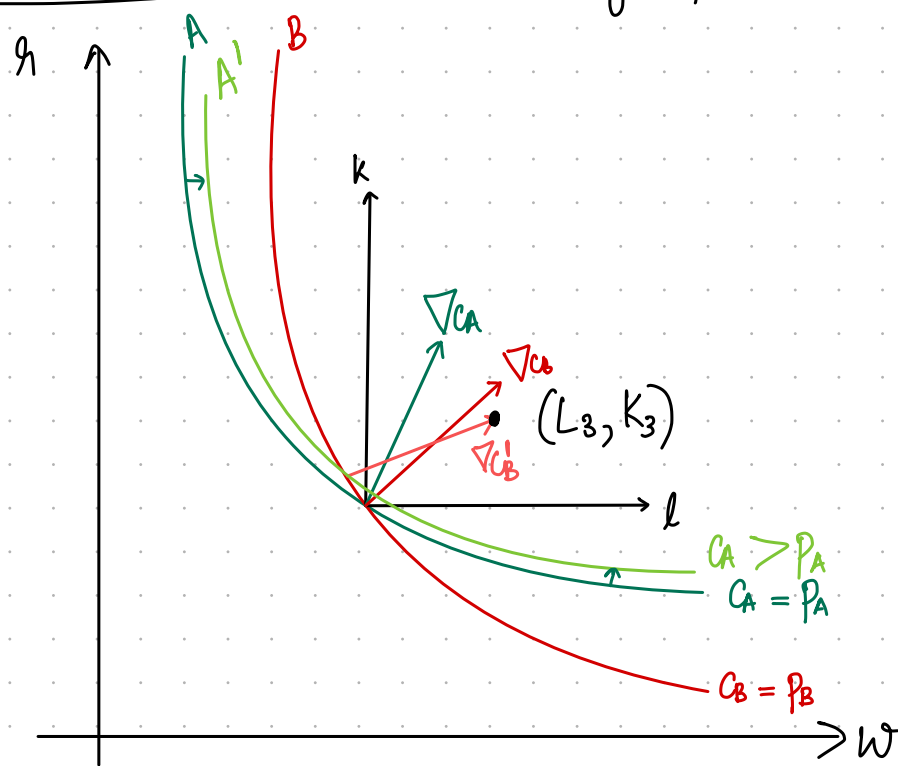

CORRECTED

@ SuengWla: This was incorrect!

See correction in next slide!

Correction: Thanks Yaling for the question!

My error during section was not paying attention to complementary slackness.

By complementary slackness, in any equilibrium:

$$\gamma_A [P_A - C_A(w, r)] = 0, \quad \gamma_B [P_B - C_B(w, r)] = 0$$

i.e. Any industry with positive production must have 0 profits.

So, for endowments (L_3, K_3) which cannot be expressed as a conical combination of ∇C_A and ∇C_B , i.e. $\nexists \gamma_A, \gamma_B > 0$ such that:

$$\gamma_A \nabla C_A + \gamma_B \nabla C_B = \begin{bmatrix} L_3 \\ K_3 \end{bmatrix}$$

$$\text{at the point : } \left. \begin{aligned} C_A(w, r) &= P_A \\ C_B(w, r) &= P_B \end{aligned} \right\} (*)$$

Consequently, in any equilibrium, it must be that equation system (*) is violated.

Since ∇c_B is closer to (L_3, K_3) , in eqbm $y_B > 0$ and $y_A = 0$.

Thus, by complementary slackness:

$$\begin{aligned} c_A(w, r) &\geq p_A \\ c_B(w, r) &= p_B \end{aligned}$$

At this point, $\exists y_B > 0$:

$$y_B \nabla c_B = \begin{bmatrix} L_3 \\ K_3 \end{bmatrix}$$

Intuition:

When K/L ratio is small, it must be that the capital intensive industry does not produce:

$$\frac{k_A}{l_A} = \frac{\partial c_A / \partial r}{\partial c_A / \partial w} > \frac{\partial c_B / \partial r}{\partial c_B / \partial w} = \frac{k_B}{l_B}$$

$$\Rightarrow y_A = 0 \quad \text{and} \quad y_B > 0!$$

2 Problems

Problem 1. Suppose in a small open economy, world output prices for good 1 and 2 are p and 1, respectively. The production functions are:

$$q_1 = k^{1/2} l^{1/2}$$

$$q_2 = k^{3/4} l^{1/4}$$

→ $C_A = P_A, C_B = P_B$

(a) Compute the equilibrium factor prices.

← $C_A, C_B, \nabla C_A, \nabla C_B$

(b) Compute $\frac{\partial w}{\partial p}$ when both goods are produced.

(c) Suppose $p = 1$. If the endowment of capital and labor are both 100, do both firms operate?

(d) Suppose $p = 1$. If the endowment of capital and labor are 100 and 400 respectively, do both firms operate?
 If (L, k) is in conic combin of $\nabla C_A, \nabla C_B \rightarrow$ diversified eqbm, else not

Problem 2. A small open economy produces two goods, A and B , using two inputs, capital (k) and labor (l). The production function for the two goods are:

$$f_A(l_A, k_A) = \min\{\alpha_A l_A, \beta_A k_A\}$$

$$f_B(l_B, k_B) = \min\{\alpha_B l_B, \beta_B k_B\}$$

Let p_A and p_B be the world output prices of good A and B respectively. Also, let the country's stock of capital and labor be $(K, L) \gg 0$. Denote the prices of capital and labor by r and w respectively. Suppose $K/L \in (1/4, 1/2)$.

(a) Let $p_A = \alpha_A = \alpha_B = 1$ and $\beta_A = 4, \beta_B = 2$. Suppose we are in the situation where both A and B are produced in positive quantities. Solve for the competitive equilibrium when both wage rate and rental rate are positive.

(b) Suppose the economy specified above is in a diversified competitive equilibrium with $w, r > 0$. What can you say regarding the factor intensity of industry A compared to industry B ? What is the effect of an increase in p_B on the equilibrium input prices?

(a) $C_A(w, r) = w + \frac{r}{4}$; $\nabla_{(w, r)} C_A = \begin{bmatrix} 1 \\ 1/4 \end{bmatrix}$

$C_B(w, r) = w + \frac{r}{2}$; $\nabla_{(w, r)} C_B = \begin{bmatrix} 1 \\ 1/2 \end{bmatrix}$

$C_A = P_A$; $C_B = P_B = ?$

$w + \frac{r}{4} = 1$; $w + \frac{r}{2} = P_B \rightarrow w^* = 2 - P_B$; $r^* = 4(P_B - 1)$

$\frac{l_A}{k_A} = \frac{\partial C_A(w, r) / \partial w}{\partial C_A(w, r) / \partial r} = 4 \quad \boxed{VS} \quad \frac{\partial C_B / \partial w}{\partial C_B / \partial r} = 2 = \frac{l_B}{k_B}$

[1] Notice that the eqbm is characterized in terms of unit cost function, so let's find it:

$$c(r, w) = \min_{k, l} \quad w l + r k$$
$$\text{s.t.} \quad k^\alpha l^{1-\alpha} \geq 1, \quad k, l \geq 0$$

$$\mathcal{L} = w l + r k + \lambda [1 - k^\alpha l^{1-\alpha}]$$

$$\text{FOC}(k): \quad r = \lambda \alpha k^{\alpha-1} l^{1-\alpha} \quad + \text{Const:} \quad k^\alpha l^{1-\alpha} = 1.$$

$$\text{FOC}(l): \quad w = \lambda (1-\alpha) k^\alpha l^{-\alpha}$$

$$c(r, w) = \left(\frac{r}{\alpha}\right)^\alpha \left(\frac{w}{1-\alpha}\right)^{1-\alpha}$$

$$\begin{cases} C_A = P_A \\ C_B = P_B \end{cases} \rightarrow r^*, w^*$$

$$\text{So, } c_1(r, w) = 2 \sqrt{r w} \quad \alpha = 1/2$$

$$c_2(r, w) = \frac{4}{3^{3/4}} r^{3/4} w^{1/4} \quad \alpha = 3/4$$

Recall (w, r) are completely characterized by

$$P_1 = c_1(w, r) \quad \text{and} \quad P_2 = c_2(w, r).$$

$$\therefore \quad P = 2 \sqrt{w r}$$

$$1 = \frac{4}{3^{3/4}} r^{3/4} w^{1/4}$$

$$\therefore q^* = \left(\frac{3}{4}\right)^{3/2} \frac{1}{p}$$

$$w^* = \left(\frac{4}{27}\right)^{1/2} p^3 \quad \longleftrightarrow$$

$$\Rightarrow \frac{\partial w^*}{\partial p} = 9 = \sqrt{\frac{4}{27}} 3p^2$$

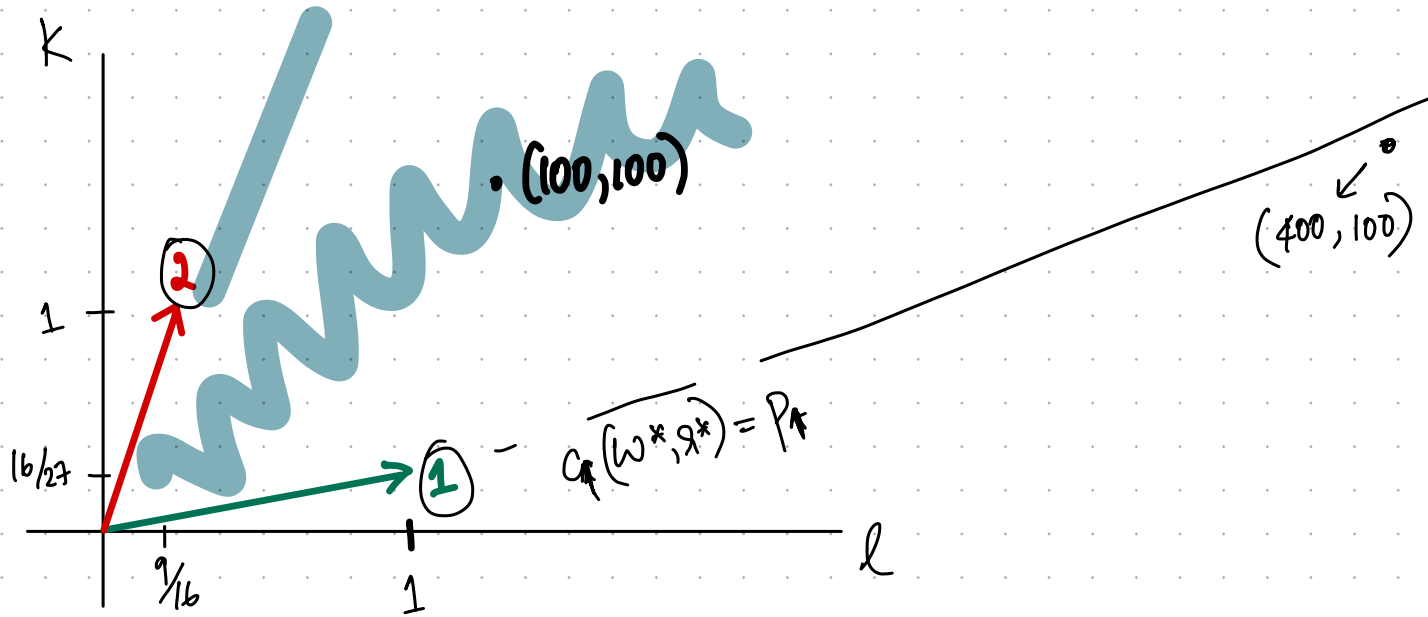

[c] To answer this, I must compute

$$\nabla_{C_1}(q^*, w^*), \nabla_{C_2}(q^*, w^*).$$

After careful algebra:

$$\nabla_{C_1} = \begin{bmatrix} \sqrt{27}/4 \\ 4/\sqrt{27} \end{bmatrix}$$

$$\nabla_{C_2} = \begin{bmatrix} 3^{-3/4} \left(\frac{27}{16}\right)^{3/4} \\ 3^{1/4} \left(16/27\right)^{1/4} \end{bmatrix}$$

$$\underset{>0}{\gamma_A} \cdot \nabla_{C_A} + \underset{>0}{\gamma_B} \nabla_{C_B} = \begin{bmatrix} 100 \\ 100 \end{bmatrix}$$

$$\boxed{2} \quad \mathcal{C}(w, r) = \min w \cdot l + r k$$

$$\text{s.t.} \quad \underbrace{\min \{\alpha l, \beta k\}} \geq 1.$$

$$\Leftrightarrow \alpha l \geq 1$$

$$\beta k \geq 1.$$

$$\mathcal{L} = w l + r k + \lambda_1 (1 - \alpha l) + \lambda_2 (1 - \beta k).$$

$$\text{FOC}(l): \quad w = \lambda_1 \alpha$$

$$(k): \quad r = \lambda_2 \beta$$

$$\text{Consts:} \quad \underline{l^* = 1/\alpha; \quad k^* = 1/\beta.}$$

$$\mathcal{C}(w, r) = w l^* + r k^* = \frac{w}{\alpha} + \frac{r}{\beta}.$$

⑥ Stolper - Samuelson: In a diversified eqbm if $p_A \uparrow$, the input that A is intensive in has its price \uparrow & other \downarrow .

$r \uparrow$ (B is intensive in k)

$w \downarrow$
